The database need to have among other data a language string. I want to do my best to avoid creating duplicate strings for every language, but need to be able to do it. For example: if I want to have translations for the name of the application in all the languages supported by my application (English, French, Japanese, German etc) I would create a unique string e.g. com.appname.en, then make my application check if that string is a static string created when the application was created and if so use it as is, if not it's a dynamically created string so create it and use it. I think it's bad design, but I'm unsure how to achieve this better. Any ideas on how to create a better design in this case? Thanks. A: If you allow multiple languages, you need to worry about syncing between multiple revisions of the string (if you allow multiple revisions). Which is a lot of work and introduces a lot of complexity. Basically, you need to have one language file for the strings you'll never change. Then you need to worry about syncing the other languages. Having said that, keep in mind that strings will almost certainly wind up in the SQLite database anyway. Having too many duplicates in the SQLite schema is not a good thing. So you're best off in the long run just creating them once in the first place. /** * Copyright (c) 2015, 2016 BEA Systems, Inc. and others * * This program and the f678ea9f9e
